A dynamic discussion on unfavorable conditions in the Polish health care system is currently going on in the mass media [4]. The public is regularly updated about the growing debt and insolvency of public health care institutions, payroll problems and a lack of funds for health services. Recent media reports have been full of information about the limits for admitting patients being exceeded in many institutions; reductions to the number of admissions, ever-growing lines and extended waiting periods for services; protests and complaints from doctors, new reimbursement regulations and plans to turn health care facilities into businesses, the introduction of additional health insurance and partial charges for treatment. Social anxiety has arisen over fears that patients will be denied access to health care. This ongoing atmosphere of suspense,
concern and anxiety is definitely influenced by the media’s negative reports on the Polish health care system [5, 6].

The survey in the present study was aimed at investigating the question of the role and position of the mass media in determining public perceptions of health care facilities in Poland.

**Material and Methods**

The survey on the media image of health care institutions in Poland was conducted during November and December of 2010. A survey specifically designed for this study was presented to a sample of 1160 people, predominantly women (75%).

The survey participants were randomly chosen students and graduates of several of the biggest institutions of higher education in Poland: the Medical University of Warsaw, the Medical University of Silesia, Warsaw University, the Warsaw University of Technology, Jagiellonian University, the Medical University of Gdańsk, the National Film School, AGH University of Science and Technology, the Wrocław University of Economics and the Catholic University of Lublin. Current students of these universities represented nearly 91% of the survey group (n = 1058); the rest were graduates, who were excluded from the study group.

Among those surveyed, women accounted for 75% and men for 25% of the sample. Among the participants 6% reside in small towns with fewer than 10,000 inhabitants, 10% are residents of cities with 50,000–100,000 inhabitants, 12% live in cities of 100,000–500,000 inhabitants, 16% live in villages and 18% reside in cities with 10,000–50,000 inhabitants. The remaining participants live in cities of more than 500,000 inhabitants (38%).

The research tool was an anonymous questionnaire posted on a website for conducting Internet research (www.ankieta.pl). The survey contained 32 various questions. After analyzing the responses, it was found that 100% of the submitted questionnaires were filled out properly.

The survey concentrated on issues related to the media image of Polish health care institutions: the participants’ interest in news about the condition of the health care system, their degree of awareness about current medical issues and the participants’ sources for news about the health care system. The questionnaire also investigated questions like the participants’ assessment of the time the mass media focus on information about Polish health care, the image of health care created by the mass media, and the news topics the participants most often see in the media, as well as the topics they most often actively seek news about. The participants were also asked about the trustworthiness of the mass media as a basis of information about Polish health care, their opinion of the media image of Polish hospitals and the impact of the mass media on their assessment and viewpoint regarding medical care in Poland.

The results were then submitted to statistical analysis using Statistica software (licensed by the Medical University of Warsaw, Poland).

**Results**

Asked to select up to 3 of their main sources of news about medical care, more than 71% of the survey respondents chose the Internet, and 65% of them chose television. For almost 1/3 of the participants (32%), doctors, nurses, pharmacists and other health care professionals are among the main sources of information. The press is a main source for 35%; their families are a main source for 28%; and the radio is a main source for 20%. For 19% of the respondents listed friends or neighbors as a main source of health care news, while 12% indicated symposia, conferences, scientific meetings, seminars and professional training. Posters, leaflets, brochures, pamphlets are a source of information for 12% of the study participants, and professional periodicals are a source for 11% (Fig. 1).

The majority of the participants in the study (68%) felt that the image of health care presented in the mass media is negative. About 17% of them feel the media image of medical care is presented objectively, and only slightly more than 1% of those surveyed consider it positive. Among the respondents 14% did not have an opinion on this subject (Fig. 2).

Fig. 3 illustrates that for 44% of the respondents the mass media are not a trustworthy source of news regarding the Polish health care system. Only 16% of the participants replied in the positive, while over 40% of the study group did not have an opinion on this subject.

The analysis of the responses also established that the size of a participant’s place of residence has no significant impact on their judgment of the reliability of the mass media as a source of information about the medical system (p > 0.05 – Table 1).

The results shown in the table indicate that 635 people answered yes or no; the rest of the participants (423) chose the answer “hard to say”. The total number of respondents in the study was 1058.

The majority of the respondents (73%) have a negative opinion of the media image of Polish health care institutions. One quarter of the respondents did not have an opinion on this question. Only 2% of the people surveyed have a positive
opinion of the media’s image of health care facilities in Poland (Fig. 4).

According to 71% of the participants in the survey, the way the mass media present news about medical care has an influence on their attitude toward and assessment of the health care system (Fig. 5). One fifth of the respondents believe that the mass media do not shape their opinions about and attitudes toward the health care system, while 9% of the participants have no opinion on this question.

Table 2 shows that there was a correlation between the participants’ gender and their assessment of the impact of the mass media on their attitudes towards the medical system. Women were considerably more likely than men to believe that
the information presented in the mass media affect their attitudes toward the health care system in Poland (p < 0.05).

**Discussion**

A patient’s individual experiences play a fundamental role in their assessment of health care institutions. Satisfied patients exhibit an increased level of loyalty to the hospitals where they were treated, and this has a particularly strong impact on its reputation in the community. The Mayo Clinic is one of the biggest medical centers in the United States, and it enjoys a very positive reputation among the public. About 520,000 patients are treated there annually, of whom 90% are satisfied with the therapy provided, which means 470,000

</table>
positively-impressed patients. According to estimates by experts from this hospital, the average patient shares information and opinions about the treatment with 39 people. If this number is multiplied by the number of positive opinions, the result is 18 m community members who have encountered a positive opinion of the Mayo Clinic [7].

However, people sometimes modify their opinions and beliefs about health care institutions on the basis of news presented in the media. Information presented in the media is highly selective, and not always consistent with the actual facts, course of events, or their causes and effects [3].

The authors concluded that the results obtained in this study indicate that the mass media play an important role in creating the image of health care institutions in Poland. The strength of the influence of the mass media on people's perceptions of health care institutions is very varied and connected with many different factors.

The authors have observed that news presented in the mass media is by nature simplified, conventionalized, often one-sided and not devoid of the journalist’s personal point of view. Time constraints mean the mass media are not able to convey the full details. In the opinion of 67.95% of the respondents to the survey in this study, the media create a negative image of health care institutions. Only 16.54% of the respondents said that the image is objective.

Given the above, cultivating good media relations should be a major part of the activities of every health care institution. However, it is very important to realize that media relations are not achieved only through press releases. It consists in arduously building databases and networking with individual editorial teams, organizing events that are really attractive from the media’s standpoint, researching and creating noteworthy news items and disseminating them in an appropriate form.
