Abstract

Background. Atherosclerosis (AS) is one of the most prevalent causes of death around the world. Since there are different types of risk factors, different types of medications focus on preventing atheromas and plaques from establishing or on preventing established plaques from growing.

Objectives. The aim of this study was to evaluate the effect of all-trans retinoic acid (atRA) on AS in a rabbit model of fat-induced AS.

Material and methods. Atherosclerosis was induced by a high-fat diet (HFD) for 75 days. Thirty rabbits were randomly divided into 5 groups. Group 1 was the negative control group and received a normal diet. The animals in the other groups were fed a HFD. Group 2 (the AS positive control group) received no drugs, Group 3 received atorvastatin orally (20 mg/kg/day), Group 4 received atRA (5 mg/kg/day, orally), and Group 5 received both drugs. All medications were started on day 45 and continued until the end of the study. Fasting blood samples were obtained for lipid profile evaluation. The aorta sections were evaluated for maximum wall and intima thickness.

Results. Oral administration of atRA, atorvastatin or their combination significantly improved serum lipid profile (p < 0.001). Atorvastatin and atRA significantly decreased serum total cholesterol and LDL-cholesterol levels in HFD (p < 0.001). No difference was found in serum HDL-cholesterol levels among the studied groups. The HFD group (Group 2 – positive control) showed significant intima irregularities with fat deposition and foamy macrophage accumulation (atheroma). Administration of atRA and atorvastatin significantly decreased the size of atherosclerotic plaques (intima thickness). The maximum vessel wall and intima thickness were significantly decreased after atRA and atorvastatin administration (p < 0.001). No difference was found between atRA and atorvastatin effectiveness, but combination therapy significantly decreased AS size in comparison to using either of the drugs alone (p < 0.001).

Conclusions. In reducing AS plaque size, atRA is as effective as atorvastatin. Additionally, the combination therapy of atRA and atorvastatin decreased AS size much more effectively, showing their synergistic effect. atRA can also improve the serum lipid profile.

Key words: atherosclerosis, high-fat diet, all-trans retinoic acid
Introduction

Atherosclerosis (AS) is one of the most prevalent causes of death around the world. It is seen as a long-term process which begins with an accumulation of fat within the vessel walls. The accumulation triggers an inflammatory process as well as platelet activation and accumulation, which subsequently leads to the formation of an atherosclerotic plaque. There are some traditional risk factors involved in the initiation or progression of plaques. Hypertension, smoking, diabetes mellitus (DM), obesity, hyperlipidemia, and infections are some well-known risk factors. Since there are different types of risk factors, different types of medications are used, but most of therapy methods are focused on preventing atheromas and plaques from establishing and on preventing established plaques from growing.

All-trans retinoic acid (atRA) is derived from vitamin A through an enzymatic process. It has antioxidant activity and is involved in cellular development, growth and differentiation. It is also known that atRA acts as an anti-inflammatory agent and can inhibit platelet function. Recent studies have uncovered some protective effects of atRA on the cardiovascular system. It has also been shown that atRA and its derivatives can inhibit DM development, and decrease body weight and lipid production by regulating fat metabolism in various organs. Considering the effects of atRA on DM and lipid metabolism, as well as its anti-inflammatory and anti-platelet activation effect, we hypothesized that atRA can be useful in the treatment of AS.

The aim of this study was to evaluate the effect of atRA on AS in a rabbit model of fat-induced AS and to compare the results with atorvastatin as a control drug.

Material and methods

Animals

Thirty male New Zealand rabbits were included in the present study. All animals were housed for 1 week in a temperature- and humidity-controlled vivarium (22 ±2°C, 30–60%) with a light/dark cycle of 10 h/14 h and access to a standard diet and water. All animal procedures were performed in accordance with the Guide for the Care and Use of Laboratory Animals (National Institutes of Health (NIH) US publication No. 85–23, revised 1985). All experiments were performed in agreement with the ethical considerations recommended by the Pasteur Institute of Iran in Tehran, and the study protocol was reviewed and approved by the Ethical Committee of the Urmia University of Medical Sciences, Iran.

Drug administration

The rabbits were randomly divided into 5 groups. Each group contained 6 rabbits. Group 1 was treated as a negative control group and was fed a normal diet for 75 days. The animals in Groups 2–5 were fed a high-cholesterol (fat) diet (HFD; 1% of body weight) for 75 days. Group 2 served as the AS positive control group and was not treated with any drugs, Group 3 received atorvastatin orally (20 mg/kg/day) starting on day 45 for 30 days (until the end of the study), Group 4 received atRA orally (5 mg/kg/day, orally) starting on day 45 for 30 days (until the end of the study), and Group 5 received both atorvastatin (10 mg/kg/day) and atRA (2.5 mg/kg/day) starting on day 45 for 30 days (until the end of the study).

At the end of the experiment, the rabbits fasted for 12 h prior to anesthesia and peripheral blood samples were obtained from the marginal vein of their ear. Then, serum samples were separated and analyzed for total cholesterol (TC), triglyceride (TG), high-density lipoprotein (HDL), and low-density lipoprotein (LDL) counts. Finally, the rabbits were sacrificed and the aorta of each rabbit was carefully resected as previously described.

Biochemical measurement

Blood samples were centrifuged at 3000 rpm for 10 min and serum samples were separated. Serum levels of TC, TG, LDL, and HDL were measured using an autoanalyzer (BT 4500; Biotecnica Instruments, Rome, Italy).

Tissue preparation

The aorta, including the ascending and descending parts, was excised and totally immersed in phosphate buffered formalin (PBF) for at least 24 h for fixation. After

Fig. 1D. Aortic tissue of a rabbit receiving atRA (Group 4), with smaller atherosclerotic plaque (area marked with *), compared to the positive control (Group 2) in Fig. 2. The vessel wall is marked with a black square. The black circle shows the vessel serosa (hematoxylin and eosin (H&E) staining, ×20 magnification)

(plaque size) of each sample were measured using an image evaluation program (Optika, Vittorio Veneto, Italy) and were compared with other samples.

**Statistical analysis**

The results are expressed as mean ± standard error of the mean (SEM). Statistical analysis was performed using SPSS v. 16.0 (SPSS Inc., Chicago, USA). Statistical evaluation of the data was performed using an analysis of variance (ANOVA). The normality of data was evaluated with the Kolmogorov-Smirnov test; p-values <0.05 were considered statistically significant.
Results

Serum lipid profile

Levels of LDL, HDL, TG, and TC were significantly higher in the HFD positive control group (Group 2) compared to the negative control group (Group 1) (p < 0.001). Our data showed that oral administration of atRA or atorvastatin, or their combination, significantly decreased TC and LDL serum levels (p < 0.001). Additionally, we found that atorvastatin reduced serum TC and LDL levels more effectively than atRA (p < 0.001), but their combination therapy showed no significant difference in effectiveness compared to atorvastatin alone (p = 0.21). No statistical difference was found in serum HDL levels among the studied groups. The details of the serum lipid profiles are included in Table 1.

Histopathological evaluation

The sample from each rabbit’s aorta was evaluated using a light microscope (Olympus BH-21; Olympus, Tokyo, Japan). In the negative control group no atheromas were identified, but the HFD group (Group 2 – positive control) showed significant irregularities on the inner surface of the aorta (intima), with fat deposition and foamy macrophage accumulation (atheroma). Oral administration of atRA and atorvastatin significantly decreased the size of the atherosclerotic plaques and intima thickness (Fig. 1A–D, 2). The maximum vessel wall and intima thickness were measured in each group and showed a significant decrease after atRA, atorvastatin or their combined administration (p < 0.001). No difference was found between atRA and atorvastatin in reducing AS size, but the combination therapy of atRA and atorvastatin significantly decreased AS size in comparison to using either drug alone (p < 0.001), (Fig. 3A, 3B).

Discussion

Derived from vitamin A, atRA is involved in some cell regulatory processes, including cell migration, healing and differentiation. Recent studies have revealed the effects of atRA on the cardiovascular system. It was shown that atRA can inhibit restenosis of a coronary artery after angioplasty. In this study, we demonstrated that oral administration of atRA in a rabbit model of fat-induced AS improved the serum lipid profile and also decreased the size of atherosclerotic plaques. We observed similar results with atorvastatin, which was used in our study as a control drug. Atorvastatin is one of the main drugs widely used to lower serum lipids levels in clinical practice.

In this study, we found atRA very effective in decreasing the size of AS. Although we found no superiority for atRA over atorvastatin in reducing AS, there are some studies which have shown that atRA is much more effective than atorvastatin. The benefits of atRA can be related to the following mechanisms: reducing lipotoxicity-induced oxidative stress, inhibiting the production of reactive oxygen species (ROS), enhancing fatty acid oxidation, activating macrophages, reducing inflammation, and inhibiting coagulatory factors. As a novel finding, we found that combination therapy of atRA and atorvastatin decreased AS size more effectively than administering either one alone. These findings suggest that atRA and atorvastatin act through different mechanisms and that their combination therapy has a synergistic effect on AS treatment.

We also found that atRA can reduce serum TC and LDL-cholesterol levels, although we found atorvastatin to be more effective in reducing serum TC and LDL-cholesterol levels than atRA. We also found no difference between atorvastatin and its combination therapy with atRA in lowering serum TC and LDL-cholesterol levels. These findings are in line with other studies on this topic.

We also found no differences in serum HDL-cholesterol levels in the compared groups. Our study had some limitations. We did not explore the underlying mechanisms through which atRA could reduced atheroma size or serum lipid levels. Some studies have explored the role of inflammation and stated that atherosclerosis is an inflammatory process. Others have shown that macrophage activation by retinoic acid...
receptors, which leads to improved antiapoptotic activity of the macrophages, can increase removal of apoptotic cells in AS plaques. In another study by Bilbija et al., an overexpression of retinoic acid target genes was shown in coronary artery disease (CAD). Bilbija et al. also reported that atRA has antiproliferative effects on cardiomyocytes and cardiofibroblasts and concluded that the antiproliferative effects of atRA may be beneficial because it may be used to delay cardiomyocyte remodeling, reduce restenosis and preserve the functions of the cardiovascular system. But in none of the related studies are the underlying signal transduction pathways, which lead to AS reduction and inhibition, clearly defined.

We found that atRA can reduce AS plaque size as effectively as atorvastatin. Additionally, their combination therapy improved their power and decreased AS size much more effectively. Our study is a novel experiment which studied the combination effect of atRA and atorvastatin on both AS and serum lipid profile. This combination effect has not been evaluated in any other study. We found that combined administration of atRA and atorvastatin had a synergistic effect only in reducing AS plaque size, but not in lowering serum lipids levels. This finding may suggest a mechanism other than lowering serum lipids levels in reducing AS plaque size. We also showed a lipid-lowering effect for atRA, although it was less effective than atorvastatin. Our results nominate atRA as a potential therapeutic agent in the treatment of AS and subsequent CAD. We suggest performing further studies to find out other therapeutic and adverse effects of atRA, as well as its mechanism of action, the optimal dosage and the route of administration. This may lead to its use in a combination therapy with statins in patients with CAD to better control the disease and reduce ischemic attacks in future.
