Abstract

Background. Cisplatin, used in cancer treatment, has toxic and apoptotic effects on the peripheral nervous system. Rutin, also known as vitamin P, has antioxidant and antiapoptotic activity.

Objectives. The purpose of this study was to investigate the biochemical and histopathologic efficacy of rutin on neurotoxic and apoptotic effects caused by cisplatin in the peripheral nervous system.

Material and methods. Twenty-four albino Wistar male rats were divided into the following 4 groups: control group (CG), only cisplatin-injected group (CIS), cisplatin and rutin 50 mg/kg (RG-50)-injected group, and cisplatin and rutin 100 mg/kg (RG-100)-injected group. Analyses were performed on sciatic nerve tissue of experimental animals. Analyses of malondialdehyde (MDA), total glutathione (tGSH), glutathione reductase (GSHRd), glutathione-s-transferase (GST), and superoxide dismutase (SOD) were performed. Caspase-3 expression in nerve tissue was also investigated. The analyzed groups were compared with CG.

Results. Biochemical investigation shows that there is a statistically significant difference between CG and only CIS and RG-50. Control group and RG-100 were found to be similar. Cisplatin-induced changes were observed in histopathological analysis of the nerve tissue. The RG-100 and CG were found to be similar. The caspase-3 expression in the neural tissue was compared between groups. Control group and CIS were found to be different. Control group and RG-100 were found to be similar.

Conclusions. Antioxidant and antiapoptotic effectiveness of rutin was detected against the toxic effects caused by cisplatin in the peripheral nerve tissue.

Key words: apoptosis, antioxidants, cisplatin, rutin, caspase-3
Introduction

Cisplatin is an old and important drug used in the treatment of cancer. It is used in many types of cancer. The main side effects are ototoxicity, nephrotoxicity and neurotoxicity, which are dose-limiting. Cisplatin causes peripheral neuropathy due to its toxic effect on peripheral nerve dorsal root ganglia. The occurrence of peripheral neuropathy causes a reduction in dose and early termination of treatment. Pathophysiological mechanisms leading to the formation of peripheral neuropathies are oxidative damage, inflammation, mitochondrial dysfunction, DNA damage, and apoptosis. Due to the absence of protection, like a blood-brain barrier in central nervous system, peripheral nerves can easily be exposed to toxic effects. Patients complaining of numbness in the form of glove-socks, clinical absence or reduction of deep tendon reflexes, decrease of distal vibration, and proprioceptive sensations are observed. Morphologic changes and deterioration of mitochondrial DNA transcription and replication in neuronal mitochondria were demonstrated during cisplatin treatment. Energy deficit, which is one of the causes of peripheral neuropathy, can take place due to the deterioration of mitochondrial functions. Cisplatin leads to an increased level of reactive oxygen species (ROS), which, in turn, causes an increase in lipid peroxidation and a decrease in catalase and glutathione peroxidase activity, consequently leading to apoptosis due to an excessive increase in caspase-3 expression.

Oxidative stress stems from an insufficient detoxification of the biological system with increased ROS. Lipid peroxidation causes many compounds that are harmful to the cells. Arachidonic acid is an omega-6 fatty acid that can be a source of hydrogen atoms for free radicals found in cell membranes. Malondialdehyde (MDA) is the major metabolite of arachidonic acid and a reliable biomarker of oxidative stress. Following the MDA level makes it possible to follow also lipid peroxidation. The MDA level in blood plasma or tissue homogenates is one of the most useful factors in determining oxidative stress. Neurotoxicity has been associated with increased oxidative stress and decreased glutathione levels. Glutathione-s-transferase (GST) is a key enzyme in the defense of the cells against oxidative stress. The main function of GST is detoxification of ROS and other oxidative stress products through reduced glutathione. Glutathione reductase (GSHRd) is responsible for providing reduced glutathione, which is one of the most important factors in controlling intracellular ROS. It acts as an electron donor for antioxidant enzymes, such as GST. Superoxide radical anion forms from free radicals in the cell after aerobic respiration. Superoxide dismutase (SOD) transforms and consumes this formed radical. As a result, it is important to prevent oxidative stress. Oxidative stress can lead to apoptosis by activating the pathways. Apoptosis occurs after the activation of caspase enzymes. Caspase-3 is at the end of this path and can be activated by both the internal and external pathway. For this reason, caspase-3 may be considered to reflect the general characteristics of apoptosis.

Rutin is an important flavonoid that is consumed in a daily diet and is found in many vegetables and fruits. It is also known as vitamin P. The protective and anti-inflammatory activity of rutin has been shown in many studies. It inhibits the peroxidation of low-density lipoprotein (LDL). It also reduces oxidative stress and inflammation and normalizes caspase-3 expression. Rutin, due to its free radical consumer efficacy, prevents the toxic effects of oxidative stress by inhibiting the effects of ROS and shows neuroprotective activity.

The toxic effect of cisplatin on the peripheral nerves was investigated in many studies. However, there was no study showing the protective effect of rutin in preventing these side effects of cisplatin. Therefore, the aim of this study was to investigate the neuroprotective and antiapoptotic effectiveness of different doses of rutin on the side effects of cisplatin in biochemical and histopathologic rat experiments. For this purpose, MDA, GST, GSHRd, and SOD levels, and caspase-3 expression were measured in experimental animals and compared with the control group.

Material and methods

Animal experiments were performed in accordance with the National Guidelines for the Use and Care of Laboratory Animals and were approved by the local animal ethics committee of Ataturk University, Erzurum, Turkey (Ethics Committee approval No. 1700238627 dated August 25, 2017).

Study animals

A total of 24 albino Wistar male rats weighing 250–265 g were used in the study. The animals were obtained from Ataturk University Medical Experimental Application and Research Center. Before the experiments, the animals were housed and fed in groups at room temperature (22°C) for 7 days under appropriate conditions.

Chemical substances

The following chemical substances were used for the experiments: cisplatin vials (50 mg/100 mL; Cisplatin-Ebewe) were provided by Liba Laboratuarları A.Ş. (Istanbul, Turkey), rutin (in tablet form) was provided by Solgar America (Leonia, USA) and thiopental sodium was obtained from IE Ulagay Ilac Sanayii Turk A.S. (Istanbul, Turkey).

Experiment groups and procedure

The animals were divided into only cisplatin-treated group (CIS), cisplatin + 50 mg/kg rutin (RG-50)-treated group, cisplatin + 100 mg/kg rutin (RG-100)-treated group, and control group without any treatment (CG).
In the course of the experiment, RG-50 (n = 6) received 50 mg/kg of rutin and RG-100 group (n = 6) received 100 mg/kg of rutin by oral gavage. In previous experimental studies, these doses of rutin were found to be effective. For CIS (n = 6) and CG (n = 6), only distilled water was intraperitoneally (ip.) injected as solvent in the same volume (0.5 mL). One hour after rutin and distilled water, cisplatin 5 mg/kg was administered ip. to all groups, except CG. It is a common practice that drugs protecting tissues against the toxic effect of cisplatin are given to experimental animals 1 h before cisplatin. Rutin and distilled water were administered once a day for 8 days. Cisplatin was administered every 2 days for 8 days.

At the end of this period, the sciatic nerve was removed from the animals, which were killed with a high dose of thiopental sodium. The attained samples were investigated biochemically and histopathologically. All results obtained from the experiments were compared with CG.

**Malondialdehyde analysis**

For the MDA measurement, we adhered to the method used by Ohkawa et al. This method is based on the spectrophotometric measurement of the absorbance of the pink complex formed by MDA with thiobarbituric acid (TBA) at high temperature (95°C) and 532 nm wavelength. The homogenates were centrifuged at 5,000 g for 20 min and these supernatants were used to determine the amount of MDA. Briefly, 250 μL of homogenate, 100 μL of 8% sodium dodecyl sulfate (SDS), 750 μL of 20% acetic acid, 750 μL of 0.08% TBA, and 150 μL of purified water were vortexed into the capped test tubes. The mixture was allowed to incubate at 100°C for 60 min, after which 2.5 mL of n-butanol was added and spectrophotometric measurements were taken. The resulting red color quantities were read at 532 nm using 3 mL cuvettes, and the MDA concentration of the samples was determined by taking the dilution coefficients into account using the standard graphic generated with the previously prepared MDA stock solution.

**Total glutathione analysis**

The amount of GSH in the total homogenate was measured according to the method used by Sedlak and Lindsay, with some modifications. The sample was weighed and homogenized in 2 mL of 50 mmol/L of Tris–HCl buffer containing 20 mmol/L of ethylenediaminetetraacetic acid (EDTA) and 0.2 mmol/L of sucrose at pH 7.5. The homogenate was immediately precipitated with 0.1 mL of 25% trichloroacetic acid, and the precipitate was removed after centrifugation at 4,200 rpm for 40 min at 4°C, and the supernatant was used to determine GSH level. A total of 1,500 μL of measurement buffer (200 mmol/L Tris–HCl buffer containing 0.2 mmol/L of EDTA at pH 7.5), 500 μL of supernatant, 100 μL of 5,5-dithiobis-(2-nitrobenzoic acid), also known as Ellman’s reagent (DTNB) (10 mmol/L), and 7,900 μL of methanol were added to a tube, vortexed and incubated for 30 min at 37°C. The DTNB was used as an chromogen and it formed a yellow-colored complex with sulfhydryl groups. The absorbance was measured at 412 nm, using a spectrophotometer (Beckman DU 500; Beckman Coulter, Brea, USA). The standard curve was obtained using a reduced glutathione.

**Glutathione reductase analysis**

Glutathione reductase activity was determined spectrophotometrically by measuring the rate of NADPH oxidation at 340 nm according to Carlberg and Mannervik method. After tissue homogenization, supernatant was used for GSHRd measurement. After the NADPH and glutathione disulfide (GSSG) addition, chronometer was on and absorbance was measured with spectrophotometric methods for 5 min by 30-minute intervals at 340 nm.

**Glutathione-s-transferase activity**

Glutathione-s-transferase activity was performed according to the method used by Sun et al. When xanthine is converted into uric acid by xanthine oxidase, SOD forms. If nitro blue tetrazolium (NBT) is added to this reaction, SOD reacts with NBT and a purple-colored formazan dye occurs. The sample was weighed and homogenized in 2 mL of 20 mmol/L phosphate buffer containing 10 mmol/L of EDTA at pH 7.8. The sample was centrifuged at 6,000 rpm for 10 min and then the brilliant supernatant was used as an assay sample. The measurement mixture containing 2,450 μL of measurement mixture (0.3 mmol/L of xanthine, 0.6 mmol/L of EDTA, 150 μmol/L of NBT, 0.4 mol/L of Na2CO3, 1 g/L bovine serum albumin), 500 μL of supernatant, and 50 μL of xanthine oxidase (167 U/L (unit /liter)) was vortexed. Then, it was incubated for 10 min. At the end of the reaction, formazan appeared. The absorbance of the purple-colored formazan was measured at 560 nm. As more of the enzyme exists, the least O2- radical that reacts with NBT occurs.

**Superoxide dismutase analysis**

Superoxide dismutase analysis performed according to the method used by Sun et al. When xanthine is converted into uric acid by xanthine oxidase, SOD forms. If nitro blue tetrazolium (NBT) is added to this reaction, SOD reacts with NBT and a purple-colored formazan dye occurs. The sample was weighed and homogenized in 2 mL of 20 mmol/L phosphate buffer containing 10 mmol/L of EDTA at pH 7.8. The sample was centrifuged at 6,000 rpm for 10 min and then the brilliant supernatant was used as an assay sample. The measurement mixture containing 2,450 μL of measurement mixture (0.3 mmol/L of xanthine, 0.6 mmol/L of EDTA, 150 μmol/L of NBT, 0.4 mol/L of Na2CO3, 1 g/L bovine serum albumin), 500 μL of supernatant, and 50 μL of xanthine oxidase (167 U/L (unit /liter)) was vortexed. Then, it was incubated for 10 min. At the end of the reaction, formazan appeared. The absorbance of the purple-colored formazan was measured at 560 nm. As more of the enzyme exists, the least O2- radical that reacts with NBT occurs.

**Histopathologic analyses**

The sciatic nerve tissue attained from the rats was fixed in 10% formalin solution for 24 h. Four micron thick sections were obtained from the paraffin blocks after routine
tissue procedure and stained with hematoxylin and eosin (H&E). All sections were evaluated using a light microscope (Olympus BX 52; Olympus, Tokyo, Japan) by a pathologist who did not know which treatment protocol was applied to samples.

**Immunohistochemical procedures**

For immunohistochemical staining, primary antibodies of caspase-3 antibody Cat: RB-1197-P0, Lot: CPP32, Ab-4 (Santa Cruz Biotechnology, Dallas, USA, TX:1/100, and Cell Signaling Technology Inc, Danvers, USA) were used. Sections were stained using a fully automated immunohistochemistry (IHC) device (Leica Bond-Max; Leica Biosystems, Melbourne, Australia). After being processed in the IHC device, sections were dehydrated through a graded series of ethanol to xylene and enclosed with a mounting medium (Entellan; Merck Millipore, Darmstadt, Germany). From the rat sciatic nerve samples incubated in 10% formalin solution for IHC processing, 4 μm thick sections were cut on a positively charged microscope slide. The results of the analysis under Olympus BX51 microscope were evaluated based on the caspase-3 staining of the sciatic nerve using the grading system described below. In this evaluation, diffuseness and intensity were considered separately. Diffuseness represents the areas the dye can be found and the intensity represents the intensity of coloration. For diffuseness, grade I represents coloration in less than 10%, grade II represents coloration 10–50%, and grade III represents coloration in more than 50% of the cells. For intensity, grade I represents mild, grade II represents intermediate and grade III represents intense coloration of the cells.

**Statistical analysis**

The results were presented for continuous variables as mean ± standard deviation (SD), median and minimum–maximum. The normality of distribution for continuous variables was confirmed with the Kolmogorov–Smirnov test. For comparison of independent continuous variables between 3 groups, analysis of variance (ANOVA) was used. Homogeneity of variances was confirmed with Levene’s test. While comparing 2 groups, least significant difference (LSD) was used as post-hoc test. The statistical level of significance for all tests was considered to be 0.05. A statistical analysis was performed using the IBM SPSS v. 19 package program (IBM Corp., Armonk, USA).

**Results**

The results of biochemical analysis in the 4 groups are shown in Table 1. When MDA (μmol/g protein) mean levels were compared in the study groups, a statistically significant difference was found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made, and CG and RG-100 were found to be similar (p = NS). Cisplatin-injected group and RG-50 were found to be different from each other, RG-100 and CG (for all other comparisons p < 0.001).

When tGSH (nmol/g protein) mean levels were compared in the study groups, a statistically significant difference was found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made, and CG and RG-100 were found to be similar (p = NS). Cisplatin-injected group and RG-50 were found to be different from each other, RG-100 and CG (for all other comparisons p < 0.001).

When GSHRd (U/g protein) mean levels were compared in the study groups, a statistically significant difference was found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made, and CG and RG-100 were found to be similar (p = NS). Cisplatin-injected group and RG-50 were found to be different from each other, RG-100 and CG (for all other comparisons p < 0.001).

When GSHRd (U/g protein) mean levels were compared in the study groups, a statistically significant difference was found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made, and CG and RG-100 were found to be similar (p = NS). Cisplatin-injected group and RG-50 was considered different (p = 0.002, p = 0.012, respectively). When

Variables are shown as mean ± standard deviation (SD), median (minimum–maximum); CG – control group, CIS – cisplatin-injected group, RG-50 – cisplatin and rutin 50 mg/kg-injected group; RG-100 – cisplatin and rutin 100 mg/kg-injected group; MDA – malondialdehyde; tGSH – total glutathione; GSHRd – glutathione reductase; GST – glutathione-s-reductase; SOD – superoxide dismutase.
When the CIS was compared with RG-50 and RG-100, a statistically significant difference was found (p = 0.006, p = 0.002, respectively). When RG-50 was compared with RG-100, a statistically significant difference was found between GSHRd averages (p = 0.018).

When the mean levels of GST (U/g protein) were compared in the study groups, statistically significant difference was found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made and CG and RG-100 were found to be similar (p = NS). When CG was compared with CIS and RG-50, the averages were statistically found to be different (p < 0.001 and p < 0.001, respectively). When the CIS was compared with RG-50 and RG-100, a statistically significant difference (p = 0.009 and p < 0.001, respectively) was found. When RG-50 and RG-100 were compared, there was a statistically significant difference between SOD averages (p < 0.001).

When the mean levels of SOD (U/g protein) were compared in the study groups, statistically significant differences were found between the groups (p < 0.001). In order to determine the group that made the difference, binary comparisons were made and CG and RG-100 were found to be similar (p = NS). When CG was compared with CIS and RG-50, the averages were statistically found to be different (p < 0.001 and p < 0.001, respectively). When the CIS was compared with RG-50 and RG-100, a statistically significant difference (p = 0.009 and p < 0.001, respectively) was found. When RG-50 and RG-100 were compared, there was a statistically significant difference between SOD averages (p < 0.001).

Biochemical examinations of CG, CIS, RG-50, and RG-100 are shown in Table 1. Histopathological examinations of CG, CIS, RG-50, and RG-100 are shown in Figure 1A–D. Figure 1A shows a healthy tissue section in CG. Figure 1B demonstrates destruction, edema and dilate blood vessels in the sciatic nerve tissue formed by cisplatin in CIS. Figure 1C illustrates only edema in the sciatic nerve tissue in RG-50. Figure 1D shows similar appearance to normal nerve tissue in RG-100.
H. Yaşar, et al. Peripheral neurotoxic effects of cisplatin

Analysis of caspase-3 expressions of CG, CIS, RG-50, and RG-100 are shown in Fig. 2A–D. Caspase-3 expression is more extensive in CIS and RG-50 than in CG and RG-100.

Discussion

The peripheral neurotoxic effects of cisplatin have been demonstrated in many studies. Neurotoxicity is the major dose-limiting side effect of cisplatin. Cisplatin increases the production of free oxygen radicals and reduces antioxidants, thereby destroying the oxidant and antioxidant balance. It also increases MDA levels.

Rutin reduces MDA levels by decreasing lipid peroxidation. In the present study, a significant increase in MDA levels was observed in the samples treated with cisplatin. By contrast, significant reductions in MDA levels appeared after the use of rutin. This result is in line with the previously mentioned studies.

Total GSH levels are reduced by the use of cisplatin. Total GSH levels increase and become similar to CG with rutin (it increases tGSH activity depending on the dose). The present study is consistent with the study by Abarikwu et al., who showed that rutin had a protective effect on tGSH levels.

Glutathione reductase is responsible for providing reduced glutathione in the cell. In the present study, GSHRd levels were decreased significantly in CIS compared to CG. GSHRd levels were significantly increased depending on the dose in both RG-50 and RG-100 after use of rutin. Thus, GSHRd levels in RG-100 reached similar values with
the CG. These results are consistent with the work of Uma-
rani et al., who observed a significant increase in GSHRd
activities after application of rutin in 50 mg/kg and rutin
70 mg/kg doses to rats.\textsuperscript{19}

In the present study, GST levels were decreased signifi-
cantly in CIS compared to CG. Glutathione-s-transferase
levels were increased in RG-50 and reached the same val-
ues as in CG with the use of rutin in 100 mg/kg dose. In
one study, cisplatin caused a significant reduction of
GST levels.\textsuperscript{21} In another study, GST levels significantly
increased with the use of rutin.\textsuperscript{22} Both results were repi-
cated in our experiment.

In the present study, SOD levels were the lowest in CIS
and were different from CG. The use of rutin in doses of
50 mg/kg and 100 mg/kg resulted in increased SOD
levels similar to those in CG. In some experiments, the use
of cisplatin decreased the SOD levels in cells.\textsuperscript{23} Superoxide
dismutase levels were observed to increase with the use
of rutin.\textsuperscript{24} Our findings are in line with the previous data.

A histopathological examination has demonstrated that
cisplatin causes toxic effects in peripheral nerves. It has
been shown that these toxic effects were improved with
increasing rutin doses and became similar to CG. In
earlier studies, the peripheral neurotoxic effect of cis-
platin in sciatic nerves had histopathological evidence.\textsuperscript{25}
It has been shown that rutin reduces neuronal damage
and gliosis.\textsuperscript{26} An increase in caspase-3 expression was observed in CIS
as well as in RG-50. Decrease in caspase-3 in RG-100 expres-
sion was similar to that in CG. It has been shown that
caspase-3 expression increases with the use of cisplatin.
A decrease in caspase-3 expression was detected in ex-
periments with animals who received cisplatin together
with rutin. The present study is compatible with the study
by Arjumand et al., who showed that rutin attenuated cis-
platin-induced apoptosis by reducing caspase-3 expression
in Wistar rats.\textsuperscript{27}

Conclusions

Our biochemical, histopathological and immunochemi-
cal investigations have confirmed that cisplatin causes oxi-
dative damage in the sciatic nerve. It has been found that
100 mg/kg of rutin reduces oxidative nerve tissue damage
induced by cisplatin more significantly than 50 mg/kg of
rutin. Our experimental results and the existing litera-
ture suggest that rutin is an important agent in preventing
dose-limiting side effects of cisplatin.
