Abstract

Background. Ischemic encephalopathy is a common clinical disease. The main treatment goal is to achieve vascular recanalization. However, after vascular recanalization, the reperfusion of fresh blood can change local cell metabolism, thus adversely affecting cell structure and function, which can result in reperfusion injury.

Objectives. To explore the effect of matrine intervention of different concentrations on JAK2/STAT3 signaling pathway and brain protection in rats with cerebral ischemia-reperfusion.

Material and methods. Healthy male Sprague Dawley rats were divided into a blank control group (20 rats), a model group (80 rats) and a sham group (20 rats). In the model group, the middle cerebral artery was occluded with suture method to establish cerebral ischemia-reperfusion model rats, which were subdivided into cerebral ischemia-reperfusion group, and 5, 10 and 20 mg/kg matrine groups, with 20 rats in each group. Indicators including neurological function score, brain infarct size, brain water content, lactic dehydrogenase activity, protein expressions of p-JAK2 and p-STAT3, as well as superoxide dismutase activity and malondialdehyde content were evaluated.

Results. Compared with cerebral ischemia-reperfusion group, all the indicators were significantly improved in the 3 matrine treatment groups in a dose-dependent manner, and protein expressions of p-JAK2 and p-STAT3 in the brain tissue and brain cell apoptosis rate were decreased with the increase of matrine concentration (all p < 0.05).

Conclusions. Matrine can significantly ameliorate the neurological function and brain edema of rats with cerebral ischemia-reperfusion, and improve superoxide dismutase activity and malondialdehyde content were evaluated.

Key words: ischemia-reperfusion injury, motor function, JAK2/STAT3 signaling pathway, neurological function, matrine cerebral
Introduction

Reperfusion injury is common in ischemic encephalopathy. After the occurrence of cerebral ischemia-reperfusion, brain cells will gradually die in the form of apoptosis; the occurrence of cerebral ischemia-reperfusion also leads to neuron necrosis and neurological deficit.

Matrine is a kind of monomeric compound extracted from *Sophora flavescens*, a legume plant. It not only has anti-tumor and anti-oxidation effect, but also protects the cardiocerebral vascular system from injuries to some extent. A previous study in rats has revealed that matrine can suppress myocardial injury induced by septic shock by inhibiting JAK2/STAT3 signaling pathway activation.

As for the effect of matrine on cerebral ischemia-reperfusion, some studies suggested that matrine could exert a protective effect on neurons of rats with cerebral ischemia-reperfusion by activating cannabinoid receptor type 2.

Janus kinase – signal transducer and activator transcription (JAK/STAT) signaling pathway is closely related to the occurrence of cerebral ischemia-reperfusion injury. A recent study has shown that the inhibition of JAK2/STAT3 signaling pathway activation can inhibit neuron apoptosis, thereby alleviating cerebral ischemia-reperfusion injury. However, there is no report on whether matrine could protect brain damage through JAK2/STAT3 signaling pathway in cerebral ischemia-reperfusion rat models.

Therefore, to further explore the neuroprotective effect of matrine in cerebral ischemia-reperfusion and its potential regulatory mechanism, we investigated the effect of different concentrations of matrine on JAK2/STAT3 signaling pathway in cerebral ischemia-reperfusion rat models.

Material and methods

Animals and material

A total of 120 healthy male SD rats, aged 8 weeks and weighed 170.68 ±7.39 g, were obtained from the Laboratory Animal Center of Hebei Medical University (certificate No. 712065). Rats were housed in a plastic case with bedding on the solid bottom at a constant temperature of 22°C and a relative humidity of 50~65% in a normal day and night circle of 12/12 h. Rats were provided free access to food and water. The operation in the modeling process conformed to the standards of the Experimental Animal Ethics Committee of our hospital, by which this study was approved.

Matrine was purchased from the Ningxia Zijinhua Pharmaceutical Co., Ltd., Wuzhong, China (batch No. 90161019; purity ≥99%). The 0.9% sodium chloride injection was purchased from the Hunan Kelun Pharmaceutical Co., Ltd., Chengdu, China (batch No. 2A16030602). TUNEL apoptosis detection kit was purchased from the Wuhan Boster Biological Technology Co., Ltd., Wuhan, China (batch No. BAO621). Primary antibodies JAK2, p-JAK2, STAT3, p-STAT3 and β-actin were purchased from the Shanghai Anyan Trade Co., Ltd., Shanghai, China. Goat anti-rabbit secondary antibody was purchased from the Abcam (Shanghai, China) Trade Co., Ltd., China (I:2,000, batch No. ab6721). Paraffin embedding center and rotary microtome were purchased from the Leica Biosystems Inc., Wetzlar, Germany. Optical microscope and microscope imaging analysis system were purchased from the Olympus Optical Co., Ltd., Tokyo, Japan. Lactic dehydrogenase (LDH), superoxide dismutase (SOD) and malondialdehyde (MDA) detection kits were purchased from the Wuhan MSK Biotechnology Co., Ltd., Wuhan, China.

Modeling

Rats were divided into a model group (80 rats), a sham group (20 rats) and a blank control group (20 rats). Rats in the blank control group were fed routinely without intervention. Rats in the model group were used to establish the model of cerebral ischemia-reperfusion. The specific modeling process was as follows. Rats were firstly anesthetized with 3 mL/kg 10% chloral hydrate. Then, the anesthetized rats were fixed on the operating table in the supine position. After routine skin preparation and disinfection, the skin was cut open lengthways through the middle of the neck, and the common carotid artery, external carotid artery and internal carotid artery were separated. Then, the common carotid artery and internal carotid artery were occluded using silk sutures. A small incision was cut on the wall of the external carotid artery at 3 mm from the arterial intersection. A nylon thread was inserted into the incision and pushed slowly towards the internal carotid artery until encountering resistance at a push-in depth of about 20 mm. At this moment, the nylon thread reached into the anterior cerebral artery and blocked the blood supply to the middle cerebral artery. Then, the external carotid artery was tightened, and the skin was sutured. Two hours later, the nylon thread was pulled outwards to the external carotid artery to develop cerebral ischemia-reperfusion. After the rats were revived, they were sent back to the cage for continuous feeding. Rats that walked towards the contralateral side or circled to their tails after operation indicated successful modeling. In the sham group, the artery of the rat was separated only without subsequent artery ligation, nylon thread insertion, etc., and other procedures, such as skin suture, were the same as in the model group.

Rats in the model group were subdivided into cerebral ischemia-reperfusion group, 5 mg/kg matrine group, 10 mg/kg matrine group, and 20 mg/kg matrine group, with 20 rats in each group. In the 3 matrine groups, matrine solutions (concentrations of 5 mg/kg, 10 mg/kg and 20 mg/kg) were intraperitoneally injected into the rats.
30 min before ischemia and 2 h after ischemia. Rats in the cerebral ischemia-reperfusion group, the sham group and the blank control group were intraperitoneally injected with the same amount of normal saline at the same time points.

**Neurological function scoring**

Neurological function was scored by Longa method 24 h after operation. Detailed scoring rules were as follows: no neurological function deficit was scored as 0; mild neurological function deficit (contralateral fore limbs could not be fully outstretched) was scored as 1; moderate neurological function deficit (rats circled to the contralateral side) was scored as 2; severe neurological function deficit (rats toppled towards the contralateral side) was scored as 3; the symptom that rats could not walk and had clouding of consciousness was scored as 4.

**Brain infarct size calculation**

After neurological function evaluation, 5 rats were randomly selected and euthanized by cervical dislocation. The brain tissue was taken out and frozen in a refrigerator at −20°C for 10 min. The infarct area was cut into sections from the coronal plane of anterior and posterior optic chiasma, with a thickness of 2 mm. Serial sections were incubated away from light in 1% 2,3,5-triphenyl-tetrazolium chloride (TTC) solution at 37°C for 20 min. The percentage of brain infarct size was calculated. Percentage of brain infarct size (%) = brain infarct size/total size of brain infarct section * 100%.

**Detection of brain water content**

Five rats in each group were randomly selected and sacrificed. Wet weight of the brain was weighed after removal of the olfactory bulb, cerebellum and lower brain stem. Then the brain was baked at 108°C for 72 h. Dry weight of the brain was weighed. Brain water content (%) = (wet weight – dry weight)/wet weight × 100%.

**Detection of SOD activity, MDA content and LDH activity in the brain tissue**

Five rats were randomly selected and sacrificed 24 h after model establishment. A part of the brain tissue was taken out and ground. The ground brain tissues were put into a test tube with the addition of 25% trypsin and incubated at 1,000 r/min for 5 min. The supernatant was collected and washed with phosphate-buffered saline (PBS) to prepare tissue suspension. LDH activity, SOD activity and MDA content in the brain tissue were measured with chemical colorimetry method, xanthine oxidase method and thiobarbituric acid method, respectively.

**Detection of brain cell apoptosis rate with TUNEL method**

Additional 5 rats were randomly selected. The brain infarct area was cut into sections to prepare specimens. Proteins of the brain tissue were digested at room temperature with 20 μg/mL protease K and rinsed 4 times with distilled water. Then, the section was incubated with TUNEL reaction mixture for 50 min and incubated with anti-fluorescein-dUTP. 3'-diaminobenzidine (DAB) coloration was performed. Five different visual fields on the infarct area were randomly selected under a light microscope to observe and count apoptotic cells. The brownish yellow showed positive apoptotic cells. Apoptosis rate (%) = number of apoptotic cells/total number of cells × 100%.

**Detection of JAK2, p-JAK2, STAT3, and p-STAT3 protein expressions measured with western blot**

Partial tissue suspension prepared during the detection of SOD activity, MDA content and LDH activity in the brain tissue was lysed with RIPA lysis buffer and mixed on the ice. The mixture was centrifuged at 1,300 r/min for 10 min. Then, the proteins were separated using 10% SDS-PAGE and transferred to polyvinylidene difluoride (PVDF) membranes. The membrane was sealed with 5% skim milk overnight at 4°C. Then the membrane was incubated with primary antibodies JAK2 (1:1,000), p-JAK2 (1:1,000), STAT3 (1:1,000), p-STAT3 (1:1,000), and β-actin (1:1,000) overnight at 4°C and horseradish peroxidase (HRP)-labeled goat anti-rabbit immunoglobulin (2nd antibody, 1:1,200) at room temperature for 1 h. The membrane was rinsed with PBS and color development was carried out using ECL developer. The results were expressed as gray value of the target band/gray value of the internal reference.

**Statistical analysis**

SPSS v. 19.0 software (IBM Corp., Armonk, USA) was adopted to analyze the collected data. The measurement data was expressed as mean ± standard deviation (SD). Comparison among groups was performed with one-way analysis of variance (ANOVA) followed by post hoc pairwise comparison using Least Significant Difference (LSD)/t test. A p < 0.05 indicated that the difference was statistically significant.

**Results**

**Neurological function scores**

Neurological function scores at 24 h after operation in the blank control group, the sham group, the cerebral ischemia-reperfusion group, the 5 mg/kg matrine group,
the 10 mg/kg matrine group, and the 20 mg/kg matrine group were 0.13 ±0.04, 0.14 ±0.05, 3.67 ±0.32, 3.05 ±0.24, 2.46 ±0.23, and 1.85 ±0.19 scores, respectively; there were no significant differences in neurological function scores between the blank control group and the sham group (p > 0.05). Neurological function scores in cerebral ischemia-reperfusion group were significantly higher than those in the sham group, the blank control group, the 5 mg/kg matrine group, the 10 mg/kg matrine group, and the 20 mg/kg matrine group. Neurological function scores were the highest in the 5 mg/kg matrine group, followed by the 10 mg/kg matrine group and the 20 mg/kg matrine group (all p < 0.05, Fig. 1).

**Brain infarct size**

Brain infarct size at 24 h after operation in the blank control group, the sham group, the cerebral ischemia-reperfusion group, the 5 mg/kg matrine group, the 10 mg/kg matrine group and the 20 mg/kg matrine group was 0%, 0%, (31.54 ±1.45)%, (25.32 ±1.21)%, (20.06 ± 1.02)%, and (15.33 ±0.97)%, respectively. Brain infarct size in cerebral ischemia-reperfusion group was significantly larger than that in the sham group, the blank control group, the 5 mg/kg matrine group, the 10 mg/kg matrine group, and the 20 mg/kg matrine group. Rats in the 20 mg/kg matrine group had the smallest brain infarct size, followed by the 10 mg/kg matrine group and the 5 mg/kg matrine group (all p < 0.05, Fig. 2).

**Brain water content**

Brain water content at 24 h after operation in the blank control group, the sham group, cerebral ischemia-reperfusion group, the 5 mg/kg matrine group, the 10 mg/kg matrine group, the 10 mg/kg matrine group, and the 20 mg/kg matrine group (all p < 0.05, Fig. 2).
Brain cell apoptosis rate at 24 h after operation in the cerebral ischemia-reperfusion group was significantly higher than that in the sham group and the blank control group (both \( p < 0.05 \)). Brain cell apoptosis rate of rats treated with matrine was reduced in dose-dependent manner; brain cell content in the 10 mg/kg matrine group and the 20 mg/kg matrine group was significantly lower than that in the cerebral ischemia-reperfusion group (both \( p < 0.05 \), Fig. 4).

### SOD, MDA and LDH levels in the brain tissue

Rats in the sham group had significantly lower MDA and LDH levels and higher SOD level than cerebral ischemia-reperfusion group (all \( p < 0.05 \)). Compared with cerebral ischemia-reperfusion group, SOD, MDA and LDH levels in the 5 mg/kg matrine group, the 10 mg/kg matrine group and the 20 mg/kg matrine group were significantly improved, and the improvement was more significant with the increase of matrine concentration (all \( p < 0.05 \), Table 1).
Protein expressions of JAK2, p-JAK2, STAT3, and p-STAT3 in the brain tissue

Rats in the cerebral ischemia-reperfusion group had significantly greater p-JAK2 and p-STAT3 protein expressions than the blank control group and the sham group (all p < 0.05). In the 5 mg/kg matrine group, the 10 mg/kg matrine group and the 20 mg/kg matrine group, p-JAK2 and p-STAT3 protein expressions were significantly decreased, and JAK2 and STAT3 protein expressions were significantly increased with the increase of matrine concentration (all p < 0.05, Table 2, Fig. 5).

Discussion

In this study, cerebral ischemia-reperfusion rat models were established using suture method and matrine intervention was administrated to rats at different concentrations to explore the curative effect of matrine on cerebral
ischemia-reperfusion and its possible mechanism. The results of neurological function evaluation indicated that rats with cerebral ischemia-reperfusion suffered from significant neurological function deficit, while matrine could relieve cerebral ischemia-reperfusion injuries in rats.

Neurons are poorly tolerant to hypoxia ischemia. Therefore, cerebral ischemia-reperfusion causes neuron necrosis and further leads to neurological function deficit.13,14 The results in this study found that matrine could improve neurological function deficit of rats with cerebral ischemia-reperfusion to some extent.

In addition, brain infarct size and brain water content of rats treated with matrine were lowered with the increase of matrine concentration, suggesting that cerebral ischemia-reperfusion in rats not only caused cerebral infarct, but also resulted in brain edema. Results of some studies indicated that matrine could decrease the degree of brain edema caused by middle cerebral artery occlusion in rats and effectively lessen brain infarct size of rats in cerebral infarction rat models,15,16 which were consistent with the results of our study, indicating that matrine could reduce the degree of cerebral edema and cerebral infarction in rats with cerebral ischemia-reperfusion.

In addition, we found that matrine can increase the activity of SOD, reduce the content of MDA, improve energy metabolism, and inhibit the increase of LDH content and the apoptosis of nerve cells caused by brain injury. When cerebral ischemia-reperfusion occurs, uncoupling of oxidative phosphorylation takes place in the mitochondria, and a great number of free radicals are generated.17 The SOD can catalyze and scavenge the disproportionate reaction of free radicals, while the change of MDA content can indirectly reflect the change of oxygen radicals; cerebral ischemia leads to the release of a large number of intracellular LDHs, which further induces brain cell damage.18,19 After the occurrence of cerebral ischemia-reperfusion, the death procedure of brain cells is activated, mainly manifesting in neuron apoptosis.20,21 These findings were in line with the results of our study, indicating that matrine can reduce the neuronal apoptosis of rats after cerebral ischemia and reperfusion to protect the rat brain tissue.

When cerebral ischemia-reperfusion occurs, the expressions of phosphorylated JAKs and STATs in the brain tissue are significantly increased.22,23 The results in our study showed that the abnormal activation of JAK2/STAT3 signaling pathway and the phosphorylation of JAK2 and STAT3 proteins in model rats might play an important role in cerebral ischemia-reperfusion injuries. Besides, after matrine intervention, rats had decreased p-JAK2 and p-STAT3 protein expressions and increased JAK2 and STAT3 protein expressions in the brain tissue, and the decrease of p-JAK2 and p-STAT3 protein expressions was more significant with the increase of matrine concentration. A study reported that inhibiting the activation of JAK2/STAT3 signaling pathway could restrain the inflammatory response induced by cerebral ischemia-reperfusion injuries and thereby lessen neuron apoptosis.24 Therefore, we hypothesize that the neuroprotective effect of matrine on cerebral ischemia-reperfusion model rats might be exerted by the activation of JAK2/STAT3 signaling pathway and the inhibition of JAK2 and STAT3 protein phosphorylation. However, we have not explored other potential mechanisms in this study. Thus, our results remain to be further verified in the future.

Conclusions

Matrine can significantly improve neurological function and brain edema of rats with cerebral ischemia-reperfusion and ameliorate SOD, MDA and LDH levels as well as apoptosis rate in the brain tissue by inhibiting abnormal activation of JAK2/STAT3 signaling pathway.
